Public Health Implications of SARS-CoV-2 Variants of Concern
Updated September 10, 2021
Evidence up to August 25, 2021

Introduction
The SARS-CoV-2 virus, responsible for COVID-19, was declared a global pandemic by the World Health Organization (WHO) in March 2020.\(^1\) As of September 9, 2021, over 222 million cases of COVID-19 have been reported worldwide and over 4.5 million people have died as a result of COVID-19 since the start of the pandemic.\(^2\) Increased numbers of COVID-19 cases are causing significant concerns around identifying optimal vaccination strategies and enforcing appropriate public health measures to manage the spread of the SARS-CoV-2 virus.

As of September 10, 2021, four variants of the original SARS-CoV-2 lineage have been declared variants of concern (VOC) by the WHO, with other variants under ongoing assessment (see Table 1).\(^3\) VOC are defined by their increased potential for transmission, presence of genomic mutations, and rapid spread across countries or regions leading to possible decreased effectiveness of public health measures.\(^4\) The increased transmissibility of VOC has led to surges in COVID-19 incidence and consequently, hospitalizations and mortality.\(^5\) Therefore, this living systematic review aims to provide a synthesis of current evidence related to VOC in the context of public health measures. This living synthesis builds on a previous rapid scoping review examining the impacts of VOC on public health and health systems conducted by this team.\(^6\)

Emerging Points of Interest
- The majority of available evidence is related to the Alpha variant; however, evidence related to public health measures and Delta is emerging rapidly
- While some of the recent modelling studies recommend extending/targeting vaccine campaigns to adolescents and younger children to reach herd immunity faster, other studies suggest vaccinating youth is only helpful if adults are vaccinated at sufficient levels
In schools, universal masking plus other non-pharmaceutical interventions (NPIs) such as physical distancing or cohorting are more effective than masking alone.

There is evolving evidence regarding changes in vaccine scheduling related to inter-dose timing and need for third dose of vaccine. Several modelling studies point to prioritizing first dose while others suggest administering second dose as soon as possible for best results. Several studies also suggest that a third dose would be beneficial, with some specifying conditions.

Universal mask wearing is recommended, particularly indoors, and double masking has the potential to improve protection against VOCs.

Some concerns exist around whether vaccinated individuals have lower engagement with NPIs, such as hand washing and physical distancing.

Some studies found that rapid and frequent testing may be an adequate substitute for quarantine of close contacts, while others recommended quicker and stricter quarantine measures.

Categories of evidence included in this report are as follows:

**Modifying approach to vaccines:** Any studies that reported on changing approaches to vaccinations such as modelling the rollout schedules or impact of NPIs in relation to vaccine schedules. Four sub-categories fell under this category:

a) Modelling potential vaccination rollout schedules
b) Evaluating past vaccination rollout schedules
c) Modelling potential vaccination rollout schedules in the presence of NPIs
d) Evaluating past vaccination rollout schedules in the presence of NPIs

**Infection prevention measures:** Any studies that reported on public health measures aimed at preventing the spread of VOC such as mask wearing, hand washing or physical distancing.

**Infection control measures:** Any studies that reported on public health measures aimed at controlling the spread of VOC such as quarantines, lockdowns, screening or testing strategies.

**Results Tables**

The following tables present a summary of evidence in relation to each of the categories described above. *The most recent additions to this living synthesis are in bold, blue font.*

</table>
| Evaluating vaccination rollout schedules | Developing mutations and reduce transmission rates\(^\text{19}\)  
- Proactive surveillance and prioritized vaccination can reduce severe illness and mortality in vulnerable groups\(^\text{20}\) with vaccinating children enhancing these benefits\(^\text{21,22}\)  
- Minimal impact of vaccinating youth (10-19yr) in reducing transmission, unless 80% of adult population is vaccinated\(^\text{23}\) | 87.5% of entire population would need to be vaccinated with a 95% efficacious vaccine using Delta’s transmission properties\(^\text{22}\) |
| Modelling different vaccine schedules in relation to NPIs | 87.5% of entire population would need to be vaccinated with a 95% efficacious vaccine using Delta’s transmission properties\(^\text{22}\) |
| **Appraised studies were of high quality** | 87.5% of entire population would need to be vaccinated with a 95% efficacious vaccine using Delta’s transmission properties\(^\text{22}\) |
| **Appraised study was of high quality** | 87.5% of entire population would need to be vaccinated with a 95% efficacious vaccine using Delta’s transmission properties\(^\text{22}\) |

- Prioritizing 1\(^\text{st}\) dose is recommended, as higher protection associated with extended schedules\(^\text{24,25}\)  
- Mixing doses (AstraZeneca + Pfizer) at 10-12 week intervals was well tolerated & improved immunogenicity compared to 2 doses of the same vaccine at the same or shorter intervals\(^\text{26}\) | 87.5% of entire population would need to be vaccinated with a 95% efficacious vaccine using Delta’s transmission properties\(^\text{22}\) |

- Targeted vaccination of 80+ age group associated with decreased mortality compared with younger group\(^\text{27}\) | 87.5% of entire population would need to be vaccinated with a 95% efficacious vaccine using Delta’s transmission properties\(^\text{22}\) |

- Prioritizing 1\(^\text{st}\) dose is recommended, as higher protection associated with extended schedules\(^\text{24}\)  
- 3\(^\text{rd}\) doses can increase antibody levels and neutralizing capability among immunocompromised individuals\(^\text{28}\) | 87.5% of entire population would need to be vaccinated with a 95% efficacious vaccine using Delta’s transmission properties\(^\text{22}\) |

- Advocate for NPIs to remain in place during vaccine roll out until sufficient population immunity\(^\text{23,29–35}\) | 87.5% of entire population would need to be vaccinated with a 95% efficacious vaccine using Delta’s transmission properties\(^\text{22}\) |

- Advocate for NPIs to remain in place during vaccine roll out until sufficient | 87.5% of entire population would need to be vaccinated with a 95% efficacious vaccine using Delta’s transmission properties\(^\text{22}\) |

- Combination vaccine (accelerated) and NPIs are required to reduce transmission rate\(^\text{16,35,36,41–43}\), | 87.5% of entire population would need to be vaccinated with a 95% efficacious vaccine using Delta’s transmission properties\(^\text{22}\) |
NPIs alongside accelerated vaccine roll out is needed to control outbreak.\textsuperscript{33,36–39} In OECD, countries fully vaccinating 40% of the population would allow for easing of containment policies.\textsuperscript{40} Further, even with the combination of Vaccine and NPIs, infections will hit school aged children the hardest during the Fall 2021.\textsuperscript{45} NPI and intense vaccine strategy targeting students is needed to substantially reduce the risk of infection.\textsuperscript{46} Increasing vaccine coverage in adolescents and regular testing essential to keep schools open.\textsuperscript{47} Stringent NPIs and third booster may be needed to stop spread of Delta.\textsuperscript{48}额

</table>
Overview of the Evidence
As of August 25, 2021, 86 studies have reported on VOC and public health measures. We include 54 studies from earlier reports (including 21 studies from an earlier rapid review and 33 from the first iteration of this report) and 32 from our updated search on August 25th, 2021. The key findings of included studies can be found in tables 2-4 above, while a more detailed summary of each study can be found in the supplementary material tables. The majority of reported evidence was related to Alpha (n=71) with fewer studies reporting on Beta (n=20 studies), Gamma (n=17 studies) and a growing volume of evidence related to Delta (n=29 studies).

Modifying Approach to Vaccine Delivery
- 448–26,26–38,40–43,45–48,55,72,93 studies reported on vaccine delivery. The majority of modelling studies explored potential vaccine rollout schedules and made recommendations for accelerated vaccination campaigns. This included studies that modelled vaccine rollout in both the presence and absence of NPIs, such as lockdown measures.
- Evidence is emerging about the value of 3rd dose or booster vaccines, particularly in the context of Delta and immunocompromised patients.
- Several modelling studies suggest infections will likely hit school-aged children the hardest and recommend different targeted vaccine schedules with continued NPIs including testing.
- NPIs are recommended to continue in tandem with a vaccine rollout schedule.

Infection Prevention Measures
- The one study that reported on handwashing and VOC found that Alpha and Beta respond similarly to ethanol and soap as wildtype SARS-CoV-2.
- One study that reported on mask wearing and VOC found that when worn correctly, masks are effective against Alpha.
- One study found no difference between cloth and surgical masks against Alpha, but another study found double masking better for protection against all VOCs.
- Seven studies reported on VOC and physical distancing measures. All studies recommended imposing strong physical distancing measures in the presence of all VOCs.
- One study found that vaccinated individuals may engage in less handwashing and physical distancing than non-vaccinated individuals but not mask wearing.

Infection Control Measures
- Fourteen studies reported on testing strategies related to VOC. Testing and routine surveillance of populations are critical to containing Alpha, Beta and Delta, even in the presence of mass vaccination campaigns. Cheaper approaches to testing are possible for detecting Alpha and Gamma.
- Twelve studies reported on quarantine and VOC. Mandatory quarantine were reported as necessary to contain Alpha and Beta. Alpha and Gamma were
identified as giving rise to more household clusters than wildtype, suggesting a need for adequate household quarantine measures.

- Three\textsuperscript{10,63,71} studies reported on isolation and VOC to contain transmission of the virus. One study was related to Alpha and Gamma respectively. Isolation duration varied across studies.
- Ten\textsuperscript{38,42–44,69,79–82,84} studies reported on lockdowns and VOC. All studies reported needing strict lockdown measures to contain Alpha or Delta. Some studies recommended longer lockdowns and more restrictive travel restrictions, while one study recommended short, strict lockdowns to mitigate the waning adherence to longer lockdowns. Two studies suggested earlier implementation of lockdown measures to limit virus spread\textsuperscript{79,84}.
- Sixteen\textsuperscript{15,22,25,36,41,46,55,59,63,68,86–91} studies reported on other NPI infection control measures and VOC. Two studies recommended modest to strong test, trace and isolate strategies as necessary to control the spread of Alpha and Delta. Two studies found that deploying a combination of NPIs is more effective than single NPIs\textsuperscript{15,22}, and multiple studies recommended employing NPIs in conjunction with vaccine rollout to mitigate the spread of Alpha or Delta.

Methods
This living synthesis is building on previous evidence gathered up to May 11, 2021. Searches for this update were run on August 25, 2021, in MEDLINE (Ovid MEDLINE All), Embase (Elsevier Embase.com), the Cochrane Database of Systematic Reviews (CDSR) and Central Register of Controlled Trials (CENTRAL) (Cochrane Library, Wiley), Epistemonikos’ L-OVE on COVID-19, and medRxiv and bioRxiv. Titles/abstracts and full text were screened independently by two reviewers. Data were double extracted using a standardized form. Studies were included if they reported on at least one of the VOC and public health measures. Critical appraisal was conducted for case-control, cohort, and cross-sectional studies using the Newcastle-Ottawa Scale for studies included in our previous rapid review\textsuperscript{6} while the appropriate Joanna Briggs critical appraisal tools were used for studies included in the living syntheses. Critical appraisal was not conducted for modelling or laboratory studies.

List of Abbreviations
COVID-19: coronavirus disease 2019
IAR: infection attack rate
NPI: non-pharmaceutical intervention/s
R: effective reproduction number
VOC: variant/s of concern
WHO: World Health Organization
